## **Assignment: Abstract Classes, Event-Driven Applications and Exception Handling**

### **Scenario**

A local travel agency, Traveless, has hired your company to implement a new flight reservation management system to improve its productivity and services. After meeting with the agency, you realize that to tackle this complex request, you must break down the solution to three major parts:

- Front-end GUI
- Backend
- Functional front end connected to the backend

### **Equipment and Materials**

For this assignment, you will need:

- Visual Studio IDE
- Supplied data files:
  - flights.csv
  - airports.csv

### **Instructions**

1. Review the scenario, and then carefully read the Traveless program Details and Program Guidelines sections of this document.
2. Working outside of class time, complete the submission sections of this assignment.
3. Review the grading criteria for the group submissions.
4. See the course schedule and/or Brightspace for due dates.

### **Submission**

1. Create the code for a program that meets the requirements described bellow.
2. Test your code against the expected output provided.
3. Check your program against the detailed marking criteria at the end of this document.

4. Submit the following to Brightspace as a group (*Only one copy is required per group, and any of the group members may submit*):
  - Github URL for your program code (invite your instructor to be a member of the project repository)
  - A copy of the test output (.txt file)

**Peer Assessment (5%)**

Each student must also complete a peer assessment of their group members. Your instructor will provide further submission details.

## Program Details

Create a functional, event-driven program that manages the travel agency's data (contained in the provided data files) and allows a user to do the following:

- Find flights:
  - A travel agent can find a flight by providing the origin airport, the destination airport and the day of the week the flight departs.
- Make a reservation:
  - A travel agent can make a flight reservation for a traveller.
  - A reservation code is generated and assigned to the traveller's name and citizenship.
- Find reservations:
  - A travel agent can find existing flight reservations using the reservation code, and/or the airline and/or the traveller's name.
- Modify an existing reservation:
  - A travel agent can update the traveller's name and citizenship.
  - An existing flight reservation can be soft-deleted, marking it as inactive and freeing up a seat on the flight.

## Detailed Requirements

When the graphical user interface is launched, the user can choose to either search flights and make a reservation, or search for and modify a reservation.

### Find Flights

The `findFlights` method receives as its input arguments: the originating airport, the destination airport, and the day of week. The method returns a List of any matching *Flight* objects. If no matches are found, the list control is empty.

### Make Reservation

When a travel agent selects a flight from the list, the text fields are populated with the selected flight code, airline, day, time and cost. The travel agent enters the traveller's full name and citizenship. The flight code, airline, day, time and cost cannot be edited. An error message is displayed if:

- A reservation is to be made but no flight is selected
- The name field is empty
- The citizenship field is empty

The `makeReservation` method receives as its input arguments: a *Flight* object, the travelers name and citizenship. An exception is thrown if the flight is completely booked, or the flight is null, or the name is empty/null, or the citizenship is empty/null. If there are no exceptions thrown a *Reservation* object is created, saved to the binary file and returned by the method.

### Find Reservations

A travel agent can search for an existing reservation that contains the specified reservation code, and/or airline and/or traveller's full name. The list is populated with any reservations that are found. Each row in the list displays the code of the corresponding reservation record.

The `findReservation` method receives as its input arguments: reservation code, airline and/or traveler's full name. The method returns a list of matching *Reservation* objects. If no matches are found, the list control is empty. If the user doesn't enter any input, then all the reservations are displayed in the list.

### Update Reservation

When a reservation in the list generated by the `findReservation` method is selected, the corresponding fields are populated, displaying the following information:

- Reservation code
- Flight code
- Airline name
- Cost

- Name
- Citizenship
- Status (active or inactive)

The only fields that can be edited are the name, citizenship and status. None of the other fields can be modified in any way by the user. After the travel agent has made changes to the reservation, they click the **Update** button. The mutator methods in the *Reservation* object are called and an error is displayed if an exception occurs.

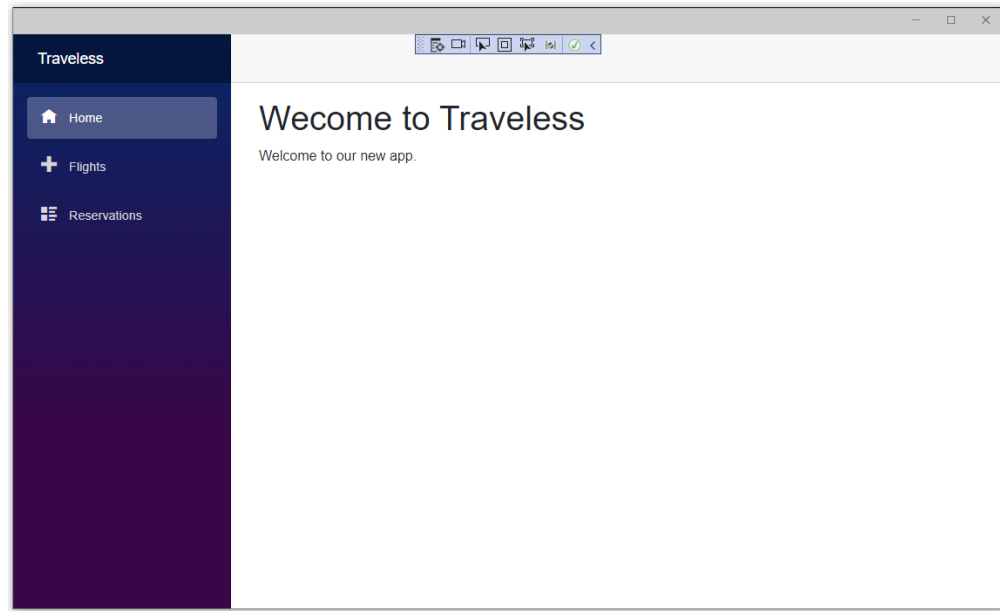

The *persist* method in the *ReservationManager* class saves all *Reservation* objects to a binary file on the hard drive.

### Notes

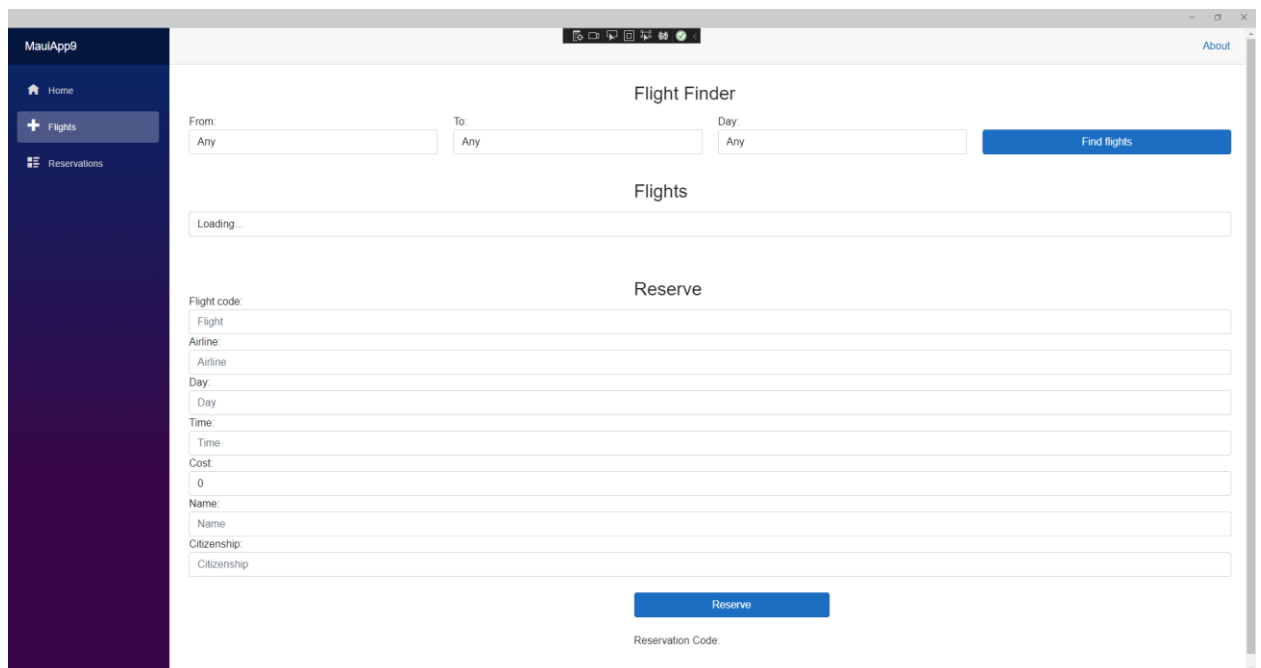

- The *ReservationManager* class generates the reservation code.
- Each reservation is for one seat only.
- The name and citizenship do not need to follow any specific format; however, they cannot be empty.
- Each problem domain class overrides the *toString()* method.
- Flight codes use the following format: (L meaning letter, D meaning digit)
  - *LL-DDDD* (e.g.: *GA-1234*)
- Reservation codes use the following format: (L meaning Letter, D meaning Digit)
  - *LDDDD* (e.g., *I1234*)
- Times are in 24-hour format: HH:MM
- A reservation that is set to **inactive** is persisted and retained when the program opens again.
